Conclusions
The frequency of blood group A is greater and the frequency of blood group 0 less in patients suffering from cancer of the stomach than in the general population of the locality in which they live. From this correlation of blood groups and cancer of the stomach it follows that there is an inherited element in the susceptibility or to protection against cancer of the stomach. This inherited element is not responsible for the known geographical differences in the incidence of cancer of the stomach in England. The environmental element which Stocks has postulated in the aetiology of cancer of the stomach is more potent than would appear from the geographical incidence of the disease in England. It is not possible from our present data to deduce whether the relationship between blood groups A and 0 and cancer of the stomach is dependent upon high- and low-incidence strains of cancer of the stomach in the general population of Great Britain or upon some specific effect of the antigens A and 0. In view of the relationship with cancer of the stomach in Great Britain it is no longer possible to regard blood groups A and 0 (in adults) as being devoid of selective value.
