Abstract—With rapid development of financial services and products, credit risk assessment has recently gained considerable attention in the field of financial risk management. In this paper, an improved credit risk assessment approach is presented. Based on the credit data from China Banking Regulatory Commission (CBRC), a multi-dimensional and multi-level credit risk indicator system is constructed. In particular, we present an improved sequential minimal optimization (SMO) learning algorithm, named four-variable SMO (FV-SMO), for credit risk classification model. At each iteration, it jointly selects four variables into the working set and an theorem is proposed to guarantee the analytical solution of sub-problem. The assessment is made on China credit dataset and two benchmark credit datasets from UCI database and CD-ROM database. Experimental results demonstrate FV-SMO is competitive in saving the computational cost and outperforms other five state-of-the-art classification methods in credit risk assessment accuracy.

Keywords: Credit risk assessment, SVM, Sequential minimal optimization (SMO), Four-variable working set

I. INTRODUCTION

The assessment of financial credit risk is emerging as an important research topic in the banking industry. The financial credit risk indicates the risk associated with financing, in other words, a borrower cannot pay the lenders, or goes into loan default. Credit risk assessment has become a particularly challenging issue for banks and financial institutions to access the performance of borrowers (customers), serving as the impetus to evaluate the credit admission or potential business failure of customers in order to make early actions. The great loss resulted from the financial distress or bankruptcy of customers usually leads to considerable criticism on the functionality of financial institutions due to the inappropriate evaluation of credit risk.

Most governments are forced to implement rescue plans for the banking systems with more effective credit risk assessment. In China, the massive credit boom poses challenge for the quality of bank assets. In fact, total bad loans reached 1.27 trillion yuan at the end of 2015, the highest since the global financial crisis, on the back of an economic slowdown and a ballooning corporate debt. An meticulous management information system is in urgent requirement. Credit risk assessment, which enables or supports an early-warning detection and fast response mechanism, is a key in this system. Since 2004, the China Banking Regulatory Commission (CBRC), which is responsible for regulation of banking industry in China, enables a reporting system for credit data collection. In recent years, CBRC has attached much importance to risk characteristics mining, custom’s behavior analysis and risk assessment model.

Generally, credit risk refers to the risk that a bank borrower or a counterparty fails to meet its obligations in accordance with the agreed terms [1]. Numerous methods have been proposed in the literature to develop accurate classifier models to predict the default risk. Many statistic and optimization models are widely applied, such as linear discriminant analysis (LDA) [2], logistic regression analysis (LRA) [3], [4], multivariate adaptive regression splines (MARS) [5] and multi-criteria optimization classifier [6], [7]. However, the assumptions embedded within these statistical models, such as the multivariate normality assumptions for independent variables, are not satisfied in reality, which makes these methods theoretically invalid for finite samples [8]. Meanwhile, these models usually fail to capture enough information of nonlinear structure of real credit data. Recent studies focus on the research of artificial intelligent (AI) techniques for credit assessment, including artificial neural networks (ANN) [9], [10], radial basis function (RBF) model [11], decision tree [12], Bayesnet [13], extreme learning machine (ELM) [14], [15], support vector machine
(SVM) [16]-[19] and so on.

Specifically, SVM is a promising approach for credit risk evaluation [20]. It realizes the theory of VC dimension on principle of structural risk minimum and overcomes the over-fitting problem compared to artificial neural network. SMO algorithm developed by Platt [21] is one of the most efficient solutions for SVM training phase. It is derived by solving a series of small quadratic programming (QP) problems, where in each iteration only two variables are selected in the working set, as the small QP problems are solved analytically such as to avoid a time-consuming numerical QP method. The technique is popular and numerous efforts are made on improving and extending the classical model. For example, Song et al [22] put forward a new strategy by selecting several greatest violating samples set for the next several optimizing steps. Cai and Cherkassky [23] generalize Platt’s SMO algorithm for SVM based multitask learning. Cao et al [24], [25] propose a parallel SMO which partitions the entire training data set into smaller subsets and then simultaneously runs multiple CPU processors to deal with each of the partitioned datasets. It’s worth mentioning that Chen et al [26] study SMO-type decomposition methods using the two-element working set under a general and flexible way, which is called Chen-SMO in this paper and is a benchmark algorithm in this paper.

The above research make remarkable improvements, but they are all still limited to the two variables working selection proposed by Platt [21]. Thinking out of the framework, in the work of Lin et al [27], they generalize the traditional SMO algorithm to three-parameters SMO and the simulation results demonstrate their algorithm’s superiority. According to these literatures, the training speed is a main limitation and important direction for making improvements of SVM algorithms. In this paper, we propose a novel and fast algorithm named four-variable sequential minimal optimization (FV-SMO). It is derived by solving a series of the QP problems with four-variable sequential minimal optimization (FV-SMO) problem into a series of smallest possible QP sub-problems, (MVP). These QP problems are solved analytically so FV-SMO algorithm approaches the optimal solution more quickly to achieve the optimization goal. Moreover, a theorem is introduced on SVM-training to guarantee the existence of analytical solution of corresponding sub-problem. The proposed algorithm makes breakthrough in the training speed, algorithm complexity and generalization ability of SVM.

The proposed method is introduced to credit risk assessment. In this paper, we focus on large corporates with the loan more than 10 million RMB from the bank of China. At first, we construct a multi-dimensional and multi-level credit risk indicator system aiming to identify the most important credit risk indicators related to the hidden default risk by considering macroeconomic environment, enterprises’ management ability and credit transaction behavior. China credit dataset is generated from CBRC monitoring system on the basis of credit risk indicator system. Two benchmark datasets, German and Darden credit datasets from UCI database and CD-ROM database respectively, are used to demonstrate the performance of the proposed method. In the numerical experiments, FV-SMO is compared with Chen-SMO in the computational cost and compared with five popular classification methods in credit risk assessment accuracy, including RBF, Multilayer-perception, Baysenet, decision tree, and Logistic regression analysis. Experimental results show that FV-SMO is competitive in saving the computational cost and outperforms other credit assessment models.

This paper is organized as follows. Section 2 introduces SMO preliminaries. Section 3 presents the improved SMO algorithm based on four-variable working set. The credit risk indicator system and dataset generation process are shown in Section 4. Followed by the numerical experiments and result analysis in Section 5. Finally, the conclusion and future research makes up Section 6.

II. PRELIMINARY

A. Sequential Minimal Optimization

Consider the problem of separating the set of training vectors belonging to two classes: \( D = \{ (x_i, y_i) \}_{i=1}^{l} \), where \( l \) is the number of training samples, \( x_i \in R^d \) is the \( ith \) training sample and \( y_i \in \{ +1, -1 \} \) is the class label of \( x_i \). SVM requires the solution of the following optimization problem:

\[
\begin{align*}
\min \quad & w(\alpha) = \frac{1}{2} \sum_{i=1}^{l} \sum_{j=1}^{l} y_i y_j \alpha_i \alpha_j K(x_i, x_j) - \sum_{i=1}^{l} \alpha_i \\
\text{s.t} \quad & \sum_{i=1}^{l} y_i \alpha_i = 0 \\
& 0 \leq \alpha_i \leq C, \quad i = 1, \cdots, l
\end{align*}
\]

(1)

Sequential Minimal Optimization (SMO) is a simple algorithm that can quickly solve the SVM. It breaks the large QP problem into a series of smallest possible QP sub-problems, using the theorem from the work of Osuna et al [29] to ensure convergence. At every step, SMO chooses two Lagrange multipliers to jointly optimize, finds the optimal values for these multipliers, and updates the SVM to reflect the new optimal values. Suppose the two chosen variables are \( \alpha_i, \alpha_j \), then...
the problem (1) can be written as the following optimization question:

\[
\min w(\alpha_i, \alpha_j) = \frac{1}{2} K_{11} \alpha^2_1 + \frac{1}{2} K_{22} \alpha^2_2 + y_1 y_2 K_{12} \alpha_1 \alpha_2 \\
- (\alpha_1 + \alpha_2) + y_1 \alpha_1 \sum_{i=3}^n y_i \alpha_i K_{1i} + y_2 \alpha_2 \sum_{i=3}^n y_i \alpha_i K_{2i} \\
st. y_1 \alpha_1 + y_2 \alpha_2 = - \sum_{i=3}^n y_i \alpha_i = c \\
0 \leq \alpha_i \leq C, \ i = 1, \ldots, l
\]

(2)

if the origin solution is \((\alpha^0_1, \alpha^0_2)\), then optimal solution can be presented as:

\[
\begin{align*}
\alpha^*_2 &= \alpha^0_2 + \frac{y_1 y_2 \nabla w(\alpha^*_1) - \nabla w(\alpha^*_2)}{K_{11} + K_{22} - 2 K_{12}} \quad (U \leq \alpha^*_2 \leq V) \\
\alpha^*_1 &= \alpha^0_1 + y_1 y_2 (\alpha^0_2 - \alpha^*_2) \\
if \quad y_1 \neq y_2: \\
\begin{cases}
U = \max(0, \alpha^0_2 - \alpha^*_1), V = \max(C, \alpha^0_2 - \alpha^*_2) \\
if \quad y_1 = y_2: \\
U = \max(0, \alpha^0_2 + \alpha^*_1 - C), V = \max(C, \alpha^0_2 + \alpha^*_2)
\end{cases}
\end{align*}
\]

(3)

The most important step of SMO is how to choose the working set. As pointed by Keerthi [31], Platt’s [21] algorithm for the selection of working set can not guarantee the maximum degree of optimization of the objective function and they used a new method named Maximal Violating Pair to do the working set selection.

B. Working Set Selection

Currently, a very popular way to select the working set is ”Maximal Violating Pair” (MVP) as follows:

\[
\begin{align*}
i \in & \arg \max_{\ell \in I_{up}(\alpha)} - y_i \nabla w(\alpha)_i \\
j \in & \arg \min_{\ell \in I_{low}(\alpha)} - y_i \nabla w(\alpha)_i \\
I_{up}(\alpha) &= \{i | \alpha_i < C, y_i = 1 or \alpha_i > 0, y_i = 1\} \\
I_{low}(\alpha) &= \{i | \alpha_i < C, y_i = -1 \text{ or } \alpha_i > 0, y_i = 1\}
\end{align*}
\]

MVP can be derived through the Karush-Kuhn-Tucker (KKT) optimality condition of (1), to derive \(\alpha^*\) for minimum \(w(\alpha)\), it implies there exists a real number \(b^*\) and two nonnegative vectors \(\lambda^*\) and \(\mu^*\) such that:

\[
\begin{align*}
\nabla w(\alpha^*) + b^* Y &= \lambda^* - \mu^*, \\
\lambda^*_i \alpha^*_i &= 0, \mu^*_i (C - \alpha^*_i) = 0, \\
0 &\leq \alpha^*_i \leq C, \lambda^*_i \geq 0, \mu^*_i \geq 0, \ i = 1, \ldots, l
\end{align*}
\]

(5)

where \(\nabla w(\alpha) = Q \alpha - e\) is the gradient of \(w(\alpha)\). The above condition can be rewritten as:

\[
\begin{align*}
\nabla w(\alpha^*)_i + b^* y_i &\geq 0, \ if \ \alpha^*_i < C \\
\nabla w(\alpha^*)_i + b^* y_i &\leq 0, \ if \ \alpha^*_i > 0
\end{align*}
\]

(6)

Since \(y_i = \pm 1\), it can be derived from (6) that \(\alpha^*\) is an optimal solution of (1) if and only \(m(\alpha^*) \leq M(\alpha^*)\).

III. AN IMPROVED SMO ALGORITHM BASED ON FOUR-VARIABLE WORKING SET

A. An important theorem

From above introduction of SMO, the key step of SMO is how to choose the two variables of the working set at each step. We propose an improved SMO algorithm named FV-SMO, the strategy is to choose four variables into the working set at each step. To advance the algorithm of FV-SMO, an important theorem is given in the following, this theorem guarantees the existence of optimal solution in our proposed algorithm FV-SMO.

**Theorem 1.** Suppose \(A = \begin{bmatrix} a_{11} & a_{12} \\ a_{12} & a_{22} \end{bmatrix} \) is a symmetry positive definite matrix, let \(x = (x_1, x_2)^T\) and \(b = (b_1, b_2)^T\), then the box constrained problem

\[
\begin{align*}
\min \quad q(x) &= \frac{1}{2} x^T A x - b^T x \\
\text{s.t.} \quad l_i &\leq x_i \leq u_i, \ i = 1, 2
\end{align*}
\]

(7)

has a unique global optimal solution:

(I) \(a_{12} \geq 0\),

\[
\begin{align*}
x^*_1 &= \min(\max(l_1, \frac{b_1 - a_{12} u_2}{a_{11}}), \max(l_1, \frac{b_1 - a_{12} u_2}{a_{12}}), u_1) \\
x^*_2 &= \min(\max(l_2, \frac{b_2 - a_{12} u_1}{a_{22}}), \max(l_2, \frac{b_2 - a_{12} u_1}{a_{22}}), l_2)
\end{align*}
\]

(9)

(II) \(a_{12} < 0\),

\[
\begin{align*}
x^*_1 &= \min(\max(l_1, \frac{b_1 - a_{12} l_2}{a_{11}}), \max(l_1, \frac{b_1 - a_{12} l_2}{a_{12}}), u_1) \\
x^*_2 &= \min(\max(l_2, \frac{b_2 - a_{12} l_1}{a_{22}}), \max(l_2, \frac{b_2 - a_{12} l_1}{a_{22}}), l_2)
\end{align*}
\]

(10)

where \(l_1 = \frac{b_1 - a_{12} u_2}{a_{11}}, l_2 = \frac{b_2 - a_{12} u_1}{a_{22}}\).

The proof detail of Theorem 1 refers to Appendix A.

B. Solving the four-variable SVM subproblem

Assuming the working set of four-variables as \(B = \{i_1, j_1, i_2, j_2\}\), and relatively the non-working set is \(N = \{1, \ldots, l\} - B\), \(\alpha, Q, e\) and \(Y\) can be decomposed:

\[
\begin{align*}
\alpha &= \begin{bmatrix} \alpha_B \\ \alpha_N \end{bmatrix}, \quad Q = \begin{bmatrix} Q_{BB} & Q_{BN} \\ Q_{NB} & Q_{NN} \end{bmatrix}, \quad e = \begin{bmatrix} e_B \\ e_N \end{bmatrix}, \quad Y = \begin{bmatrix} y_B \\ y_N \end{bmatrix}
\end{align*}
\]

(11)
The problem (1) is equivalent to the following sub-problem:

\[
\min w(\alpha) = \frac{1}{2} \alpha^T B Q B \alpha + (Q B N \alpha - e B)^T \alpha + \text{const}
\]

\[
+ (Q B N \alpha - e B)^T \begin{bmatrix}
\alpha_1 \\
\alpha_2 \\
\alpha_3
\end{bmatrix}
\]

\[
\begin{bmatrix}
Q_{11} & Q_{12} & Q_{13} \\
Q_{21} & Q_{22} & Q_{23} \\
Q_{31} & Q_{32} & Q_{33}
\end{bmatrix}
\]

s.t. \( y_i \alpha_i + y_j \alpha_j + y_k \alpha_k + y_l \alpha_l = -y_{ij} \alpha_N \)

\( 0 \leq \alpha_i, \alpha_j, \alpha_k, \alpha_l \leq C \)

(12)

When solving (12), Chen et al in [26] study sequential minimal optimization type decomposition method under a general and flexible way of choosing the two-element working set, the iterative relationship is introduced as:

\[
a_{i_{k+1}} = a_i - y_i d_i, \quad a_{j_{k+1}} = a_j + y_j d_j
\]

(13)

Based on Chen’s idea, we consider the iterative relationship:

\[
\begin{align*}
\alpha^{k+1}_{i_1} &= \alpha^k_{i_1} - y_i d_i, \quad \alpha^{k+1}_{j_1} = \alpha^k_{j_1} + y_j d_j, \\
\alpha^{k+1}_{i_2} &= \alpha^k_{i_2} - y_i d_i, \quad \alpha^{k+1}_{j_2} = \alpha^k_{j_2} + y_j d_j
\end{align*}
\]

(14)

so (12) is rewritten as:

\[
\min w(\alpha) = \frac{1}{2} [d_1 \  d_2]
\begin{bmatrix}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{bmatrix}
\begin{bmatrix}
d_1 \\
d_2
\end{bmatrix}
\]

s.t. \( l_1 \leq d_1 \leq u_1, \quad l_2 \leq d_2 \leq u_2 \)

(15)

where

\[
\begin{align*}
a_{11} &= K_{i_1 i_1} + K_{i_1 j_1} + 2K_{i_1 j_1} \\
a_{12} &= K_{i_1 i_2} - K_{i_1 j_2} - 2K_{i_2 j_1} \\
a_{22} &= K_{j_2 j_2} - 2K_{i_2 j_2} \\
b_1 &= y_i \nabla w(\alpha^k)_{i_1} - y_i \nabla w(\alpha^k)_{j_1} \\
b_2 &= y_j \nabla w(\alpha^k)_{i_2} - y_j \nabla w(\alpha^k)_{j_2}
\end{align*}
\]

C. An improved SMO algorithm based on four-variable working set

Here we employ the method of MVP to select the working set in the FV-SMO:

\[
\begin{align*}
i_1 &\in \arg \max_{t \in I_{low}(\alpha)} -y_t \nabla w(\alpha) \\
\{i_1, j_1\} &\in \arg \min_{t \in I_{low}(\alpha) \setminus \{i_1, j_1\}} -y_t \nabla w(\alpha)
\end{align*}
\]

(18)

To sum up, the FV-SMO algorithm is motivated that multivariable coordinated optimization could reduce the number of iterations and training time. This method is derived by solving a series of the QP subproblems with four points and these subproblems are solved analytically. Thus, it can approach to the optimal solution much quickly, and further improve the performance of SMO-type learning algorithm greatly. We formally investigate the possible advantages by experiments analysis in the following section. The FV-SMO formal algorithm can be stated as follows:
Algorithm FV-SMO
Given dataset: $x_i, y_i, i = 1, 2, ...n$
Result: $\alpha_i$ solved by an analytical method
While it does not reach convergence, do:
step1: Given $\varepsilon > 0$ and $\alpha^0 = 0$. Set $k = 0$.
step2: If $m(\alpha^k) - M(\alpha^k) \leq \varepsilon$, stop; Otherwise by the above MVP to find a four-variable working set $B = \{i_1, i_2, j_1, j_2\}$.
Define $N \equiv \{1, \cdots , l\} - B$, $\alpha^k_B$ and $\alpha^k_N$ as sub-vectors of corresponding to $B$ and $N$, respectively. And using formulas (16)-(17) to get $d_1^k$, $d_2^k$, further by (14) derive optimal solution $\alpha^k_B$.
step3: Gradient update: $\nabla w(\alpha^{k+1}) = \nabla w(\alpha^k) + diag(Y)[(-K(:, i_1) + K(:, j_1))d_1^k + (-K(:, i_2) + K(:, j_2))d_2^k]$.
step4: Set $k = k + 1$ and go to step2.
end

IV. CHINA’S CREDIT RISK INDICATOR SYSTEM

As the economy skyrocketed in the past few years, China’s financial system has grown exponentially. The assets managed by banks once grew more than 25% a year during the period of the massive fiscal stimulus plan to combat the global financial crisis. Only in the first two months of 2016, bank credit rose a significant 28% to RMB 3351 billion compared with the same period in previous year. Nowadays, China’s economy is in the process of reform and structural adjustment, the banking institutions’ risk management ability becomes increasingly important in the development.

Since 2004, CBRC has established a data collection system for monitoring the customers’ loan behaviors monthly. Despite the data accumulated for more than ten years in the monitoring system, existing studies do not lend themselves to modeling the risk factors for big data and provide little guidance to policy makers in terms of loan application decision. Many experts point out that the key risk is coming from large corporate borrowing and from the reduction of profitability stemming from financial liberalization and heightened competition. In this paper, we focus on large corporates with loan more than 10 million RMB. We first construct a multi-dimensional and multi-level credit risk indicator system aiming to find the most important credit risk characteristics which will lead to the serious default risk, followed by the generation of China credit dataset.

A. China credit risk indicator system

First of all, the external factors are explored including macroeconomic, industry and region. The majority of China’s credit is accumulated in fields of government infrastructure, real estate construction and large state-owned corporates. This leads to complicated causal relationship between credit risk, macroeconomic and monetary policy. It is reasonable to take macroeconomic factors as priority into consideration, such as GDP growth rate, M2 growth rate, interest rate and so on. Meanwhile, the overall situation of an industry closely relates to its credit behavior, three specific indicators are extracted: industry profit margin, concentration of loan investment and default rate of industry. According to different regional credit markets, implement differentiated regional credit policy also plays an important role in management process, so it is necessary to explore the regional dimensional factor. Regional industrial structure, regional economic development situation and regional default rate are investigated.

Second, we focus on the corporates’ management ability. The enterprises’ production, operation state and business behaviors directly affect the efficiency of credit funds use. The indicators related to operation situation, solvency and credit level are explored. Taking operation situation into consideration, corporates’ capital scale and long-term viability of operation can be figured out. Generally, the operation situation can be expressed by measuring market capitalization, assets, cash flow and others. Here key financial indicators are investigated, such as asset scale, debt ratio, current ration and so on. Making the analysis of solvency promotes to clarify the ability of sustainable management and predict the future revenue, such as equity ratio, loan asset ratio are considered. For credit level, it is measured by the risk signals that given by the loan institutions as existing credit judgment towards the corporates, which could also contribute to the identity of default behavior in the future.

Third, the credit data from CBRC makes the corporates’ transaction data mining possible. Two aspects including transaction behavior and association risk are mined. The customers’ past loan behavior acts as the most convincing evidence for determining whether a customer should be granted good credit or not. The quantity and quality of loan, the lending bank information are explored as well. In addition, the credit interconnection among corporates are getting increasingly closer in recent years. The credit association promotes corporates to share capital, acquire excessive credit or escape from risk investigation. These behaviors increase the difficulty of credit

regulation and needs particular attention. Four major association relationship are investigated, including legal person, guarantee, stockholder and other business associates.

Finally, the whole indicator system is constructed with three overall dimension: external factors, management ability and trading behaviors. The second level includes 14 indicators including: macroeconomic, industry, region, operation situation, solvency, credit level, quantity, quality, bank, legal person, stockholder, business associates and guarantee. The third level is extended including 124 detailed indicators, such as regional default rate, loan bank concentration and so on. These indicators are not only extracted from the original data, but also derived from the analysis and mining of customer’s transaction behavior. For instance, it is regarded as a risk signal if a customer often pay off the loan of one bank using the loan from other banks. Due to the limit of space, part of these indicators are listed in Figure 1.

B. Generation of China credit dataset

After the credit risk indicator system analysis, China credit dataset is extracted from the CBRC’s credit data. Data preprocessing is implemented for converting the primary data to format. The techniques including cleaning, integration, transformation are used to process the dirty, incomplete and inconsistent data. Another important issue that needs to be clarified is the definition of default risk, we define a customer default if it is behindhand with its payment for more than three months. Once a default occurs in the credit history, the customer is marked as a positive sample.

The purpose of feature selection [32], [33], [34] is to filter out unrepresentative features from a given dataset, which is critical for a successful credit default classification model. For the credit risk indicator system as stated in Section 4, T-test and Wilcoxon signed ranks tests are used to distinguish indicators objectively. The criterion is whether the indicator changes significantly prior to the default occurs. 54 indicators are picked out by the single indicator test. Next, stepwise regression pares down the these indicators to eliminate the collinearity. Finally, 16 most representative indicators are chosen for the assessment model.

After data preprocessing and feature selection, the sample of China credit dataset has 60126 instances, 1822 default (positives) and 58324 non-default (negatives). The number of negatives is almost 32 times the size of positives. Since high imbalance of the data could seriously affects the model performance, downsample method is adopted to construct

For Darden corporate credit dataset, it is from the CD-ROM database and includes 132 companies (66 non-risk cases and 66 risk cases). A total of 25 financial variables are computed for each of the 132 companies using data from the Compustat and from the Moodys Industrial Manual. The information of all datasets is shown in Table I.

B. Complexity comparison

To assess the complexity efficiency of the FV-SMO algorithm, RBF kernel $K(x, y) = \exp(-\gamma * \|x - y\|^2)$ is chosen. All experiments are run on PC (Intel(R)core(TM)5/RAM16.0GB) in MATLAB 2016. The stopping condition $\epsilon$, and the hyper parameters of $C$ and $\gamma$ need to be given. A superior algorithm should have stable and better performance with the changing parameters and different stopping condition. In Table II, $C$ and $\gamma$ are set at 1, the stopping condition $\epsilon$ ranges from 0.1 to $1 \times 10^{-10}$. In Table III, $\gamma$ is set at 1 and $\epsilon$ is set at $1 \times 10^{-10}$.

$C$ ranges from 0 to 5. From the results of Table II and Table III, the number of FV-SMO’s iterations is obviously fewer than Chen-SMO. Student T-test and Wilcoxon’s signed rank test are taken to identify the statistical significance of the results comparison. All the P values of experiments are statistical significant which demonstrate the superiority of FV-SMO.

As m-M can reflect the optimizing convergence rate for current iterating rate more intuitive, Figs. 3-5 depicts the curves of m-M versus the iterating steps. The curves with blue and red colour are the results of FV-SMO and Chen-SMO, the $C$ and $\gamma$ are set at 1, $\epsilon$ is set at $1 \times 10^{-10}$. In most iterating steps, we can see the declines of objective m-M in FV-SMO are superior to that in Chen-SMO. The convergence speed of FV-SMO is significantly faster than that of Chen-SMO, which once again demonstrates the proposed FV-SMO outperforms Chen-SMO in the sense of faster convergence.

The results of classification accuracy are shown in Table IV-VI. Firstly, the Total accuracy of FV-SMO generally outperforms other classifiers for both China and German datasets, followed by MLP for China dataset and Bayesnet for German dataset. But for Darden dataset, FV-SMO is second only to Logistic. In terms of Type1 accuracy, FV-SMO is superior to other classifiers for China and Darden datasets, ranking second (0.453) on German dataset, the best is Bayenet (0.483). Then from the Type2 accuracy viewpoint, RBF has the best performance (0.887) for China dataset and FV-SMO has the best performance (0.903) for German dataset. FV-SMO has a relatively poor performance (0.622) compared to best result of Logistic (0.819) for Darden dataset.

C. Accuracy comparison

Classification accuracy is the basic and decisive aspect in choosing the credit classification model. In order to check the performance of FV-SMO, we compare FV-SMO with five popular classification approaches in classification accuracy. The benchmark approaches include RBF, Multiplayer-perception, Bayesnet, Decision tree, and Logistic. For each approach, we adjusted the parameters to achieve the best classification accuracy. The five models are run using Weka 3.6. Given a classifier and an instance, there are four possible outcomes: if the instance is positive and it is classified as positive, it is counted as a true positive (TP); if the instance is negative and it is classified as positive, it is counted as a false positive (FP), the definition of TN and FN is the same. Six well known accuracy criteria are used to evaluate the performance of the classifier as follows:

(i) The total classification accuracy rate

\[
Total \ accuracy = \frac{TP+TN}{TP+FP+TN+FN}
\]

(ii) The identification rate of "bad" creditors

\[
Type1 \ accuracy = \frac{TP}{TP+FN}
\]

(iii) The identification rate of "good" creditors

\[
Type2 \ accuracy = \frac{TN}{TN+FP}
\]

(iv) How accurately of "bad" creditors have been classified

\[
Precision = \frac{TP}{TP+FP}
\]

(v) The mixed measure of classification

\[
F1-measure = \frac{2}{\frac{1}{Precision} + \frac{1}{Recall}}
\]

In practical credit risk management, Type1 accuracy measures the identification rate of "bad" creditors, which means that the potential customer who is actually un-creditworthy is denied credit. The Type2 accuracy measures the identification rate of "good" creditors, which means a creditworthy customer is granted by the decision maker. Precision measures what the fraction is correctly categorised in all the positive predictions. F1-measure is a mixed criteria with a combination of Precision and Recall. Clearly, higher of these criteria corresponds to better predictive performance of classifier.

The receiver operating characteristic curve (ROC) [36] is a two-dimension graph in which true positive rate is plotted on the Y-axis and false positive rate is plotted on the X-axis. AUC based on the area under the ROC curve is another measure of classifier. Generally, a model with a larger AUC will have a better average performance.

</table>

- **Precision(%) rank**: Model name followed by their precision ranking.
- **F1-measure(%) rank**: Model name followed by their F1-measure ranking.
- **ROC curve space rank**: Model name followed by their ROC curve space ranking.
For the measurement of Precision and F1-measure, FV-SMO also yields a very good performance. Precision of FV-SMO ranks the second with a tiny gap (0.004) behind RBF on China dataset. F1-measure of FV-SMO ranks the second behind Logistic on Darden dataset. For other comparisons, FV-SMO ranks the first. The area under the receiver operating characteristic ROC curve is applied as another performance measurement. Figure 6 - 8 show the performance of the ROC curve for the three datasets. It is obvious that FV-SMO outperforms other models in terms of ROC.

Comparing with the empirical results of the three datasets, it is seen that Type2 accuracy is better than Type1 accuracy for China and German datasets, which means it is more difficult to catch the “bad” creditors from all the applicants, especially for the unbalanced dataset of German. But the result is inconsistent on Darden dataset. One possible reason is that different credit markets have different credit characteristics and the other is more nonlinearity in China and German datasets than that in Darden dataset.

Meanwhile, there is an interesting finding from Type1 accuracy and Type2 accuracy. For example, RBF ranks the first of Type2 accuracy (0.887), but performs the worst of Type1 accuracy (0.419) on China dataset. For German dataset, MLP and J48 have a poor performance in terms of Type1 accuracy, only 0.29 and 0.21, but get quite high performance of Type2 accuracy, 0.889 and 0.896, ranking top three with a slight difference to the FV-SMO. It is shown that some classifiers have the tendency to get a high recognition rate of majority class by predicting most samples as the “good” ones, especially on the imbalanced dataset, making the classifiers unsuitable for the credit risk assessment. From the above analysis, it can be concluded the proposed FV-SMO is promising in comparison with the other five popular classification approaches.

VI. CONCLUSION AND FUTURE WORK

In this paper, we present a novel SMO learning algorithm on a four-variable working set for classification model and applied it to China credit dataset and two benchmark datasets. This method derived by solving a series of the QP sub-problems with four variables and these sub-problems are solved analytically so that the proposed method approaches to the optimal solution more quickly. Numerical results demonstrate that the proposed method has faster speed with statistical significance. Besides, experimental results also illustrate that FV-SMO can get the satisfactory performance in the classification accuracy, which provides compelling evidence of the advantages of FV-SMO. Given its encouraging performance, we are aiming to extend the algorithm to solve the problem of multi-class and regression problem instead of the binary classification.

Another contribution of this work is the multi-dimensional and multi-level credit risk indicator system. According to our knowledge, it is the first attempt to build the comprehensive indicator system on real credit data of China’s banking. The system can not only help the banking managers and the audience of this paper to understand the overall situation of China’s credit risk, but also screen out the key indicators that should be monitored by the policy makers. For future work, we could explore this system for more credit risk management applications.

REFERENCES

Theorem 1. Suppose \( A = \begin{pmatrix} a_{11} & a_{12} \\ a_{12} & a_{22} \end{pmatrix} \) is a symmetric positive definite matrix, let \( x = (x_1, x_2)^T \) and \( b = (b_1, b_2)^T \), then the box constrained problem

\[
\min q(x) = \frac{1}{2} x^T A x - b^T x
\]

s.t. \( l_i \leq x_i \leq u_i, \ i = 1, 2 \)

has a unique global optimal solution as follows

(I) \( a_{12} \geq 0 \),

\[
\begin{align*}
    x_1^* &= \min (\max(l_1, x_1^*, \frac{b_1-a_{12}u_2}{a_{11}}), \max(\frac{b_1-a_{12}l_2}{a_{11}}, l_1)) \\
    x_2^* &= \max(\min(l_2, x_2^*, \frac{b_2-a_{12}u_1}{a_{22}}), \min(\frac{b_2-a_{12}l_1}{a_{22}}, l_2))
\end{align*}
\]

(II) \( a_{12} < 0 \),

\[
\begin{align*}
    x_1^* &= \min (\max(l_1, x_1^*, \frac{b_1-a_{12}u_2}{a_{11}}), \max(\frac{b_1-a_{12}l_2}{a_{11}}, l_1)) \\
    x_2^* &= \max(\min(l_2, x_2^*, \frac{b_2-a_{12}u_1}{a_{22}}), \min(\frac{b_2-a_{12}l_1}{a_{22}}, l_2))
\end{align*}
\]

where \( x_1^* = \frac{b_1-a_{12}u_2}{a_{11}l_1} \) and \( x_2^* = \frac{b_1-a_{12}l_1}{a_{21}} \).

Proof: Since problem (19) is strict convex, suppose \( x^* = (x_1^*, x_2^*)^T \) is the unique global optimal solution of (19), then
we only prove that \( x^* \) satisfies the following KKT conditions:

\[
\begin{align*}
\nabla q(x^*)_i &= 0, \quad l_i < x_i^* < u_i \\
\nabla q(x^*)_i &\geq 0, \quad x_i^* = l_i \\
\nabla q(x^*)_i &\leq 0, \quad x_i^* = u_i, \quad i = 1, 2
\end{align*}
\]

The gradient of function \( q(x) \) is

\[
\nabla q(x) = \begin{pmatrix}
a_{11} & a_{12} \\
a_{12} & a_{22}
\end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} - \begin{pmatrix} b_1 \\ b_2 \end{pmatrix}
\]

It is easy to verify that \( (\overline{x}_1, \overline{x}_2)^T \) is the solution of equation \( \nabla q(x) = 0 \).

Since \( A \) is a positive definite matrix, we have \( a_{11} > 0, \quad a_{22} > 0 \) and \( det(A) > 0 \).

(I) For \( a_{12} \geq 0 \), there are nine cases discussed as follows:

Case 1: If \( l_1 \leq \overline{x}_1 \leq u_1, \quad l_2 \leq \overline{x}_2 \leq u_2 \), then \( x^* = (\overline{x}_1, \overline{x}_2)^T \).

Proof: It is clear that \( \nabla q(x^*) = 0 \), that is, \( x^* \) satisfies KKT condition.

Combining \( l_1 \leq \overline{x}_1 \leq u_1 \) and \( l_2 \leq \overline{x}_2 \leq u_2 \), we have

\[
\begin{align*}
0 < a_{11}\overline{x}_1 + a_{12}\overline{x}_2 &\leq b_1 < a_{11}x_1 + a_{12}u_2, \\
0 < a_{12}\overline{x}_1 + a_{22}\overline{x}_2 &\leq b_2 < a_{12}u_1 + a_{22}x_2
\end{align*}
\]

which implies

\[
\frac{b_1 - a_{12}u_2}{a_{11}} \leq x_1^* \leq \frac{b_1 - a_{12}l_2}{a_{11}}, \quad \frac{b_2 - a_{12}u_1}{a_{22}} \leq x_2^* \leq \frac{b_2 - a_{12}l_1}{a_{22}}
\]

Therefore \( x^* = (\overline{x}_1, \overline{x}_2)^T \) is the unique global optimal solution of (19), and it has the form of expression (20).

Case 2: If \( \overline{x}_1 \geq u_1 \) and \( \overline{x}_2 \geq u_2 \), then \( x^* = (u_1, u_2)^T \). Proof:

By \( \overline{x}_1 \geq u_1 \) and \( \overline{x}_2 \geq u_2 \) we have

\[
\begin{align*}
a_{11}\overline{x}_1 + a_{12}\overline{x}_2 &\leq a_{11}u_1 + a_{12}u_2 < b_1, \\
a_{12}\overline{x}_1 + a_{22}\overline{x}_2 &\leq a_{12}u_1 + a_{22}u_2 \leq b_2
\end{align*}
\]

which implies

\[
\overline{x}_1 \leq \frac{b_1 - a_{12}u_2}{a_{11}}, \quad \overline{x}_2 \leq \frac{b_2 - a_{12}u_1}{a_{22}}
\]

\[\nabla q(x^*) \leq 0\]

namely, \( x^* = (u_1, u_2)^T \) satisfies KKT condition and has the form of expression (20). Therefore, \( x^* \) is the unique global optimal solution of (19).

Case 3: If \( l_1 \leq \overline{x}_1 \leq u_1, \quad \overline{x}_2 > u_2 \), then \( x^* = (\min(\frac{b_1 - a_{12}u_2}{a_{11}}, u_1), u_2)^T \). Proof: From \( l_1 \leq \overline{x}_1 \leq u_1, \quad \overline{x}_2 > u_2 \) we get

\[
\begin{align*}
\overline{x}_1 &\leq \frac{b_1 - a_{12}u_2}{a_{11}} \leq \frac{b_1 - a_{12}l_2}{a_{11}}, \\
\overline{x}_2 &\leq \frac{b_2 - a_{12}u_1}{a_{22}} \leq \frac{b_2 - a_{12}l_1}{a_{22}}
\end{align*}
\]

Further we have

\[
\begin{align*}
\nabla q(x^*)_1 &= 0, \quad l_1 < \frac{b_1 - a_{12}u_2}{a_{11}} < u_1, \\
\nabla q(x^*)_1 &\leq 0, \quad \frac{b_1 - a_{12}u_2}{a_{11}} \geq u_1, \\
\nabla q(x^*)_2 &\leq 0
\end{align*}
\]

that is, \( x^* = (u_1, u_2)^T \) satisfies KKT condition and has the form of expression (20). Therefore, \( x^* \) is the unique global optimal solution of (19).

Case 4: If \( \overline{x}_1 < l_1 \) and \( \overline{x}_2 > u_2 \), then

\[
x^* = \begin{cases} 
\min(\frac{b_1 - a_{12}u_2}{a_{11}}, u_1), u_2 \end{cases}^T, \quad \frac{b_1 - a_{12}u_2}{a_{11}} > l_1 \\
(l_1, \min(\frac{b_2 - a_{12}l_1}{a_{22}}, l_2), u_2)^T, \quad \frac{b_1 - a_{12}u_2}{a_{11}} \leq l_1
\]

Proof: We discuss in two cases.

First, if \( \frac{b_1 - a_{12}u_2}{a_{11}} > l_1 \), then by \( \overline{x}_1 < l_1 \) and \( \overline{x}_2 > u_2 \) we get \( \overline{x}_2 > u_2 \) and \( x^* = (\min(\frac{b_1 - a_{12}u_2}{a_{11}}, u_1), u_2)^T \). Further we have

\[
\begin{align*}
\nabla q(x^*)_1 &= 0, \quad l_1 < \frac{b_1 - a_{12}u_2}{a_{11}} < u_1, \\
\nabla q(x^*)_1 &\leq 0, \quad \frac{b_1 - a_{12}u_2}{a_{11}} \geq u_1, \\
\nabla q(x^*)_2 &\leq 0
\end{align*}
\]

that is, \( x^* = (\min(\frac{b_1 - a_{12}u_2}{a_{11}}, u_1), u_2)^T \) satisfies KKT condition and has the form of expression (20). Therefore, \( x^* \) is the unique global optimal solution of (19).

Second, if \( \frac{b_1 - a_{12}u_2}{a_{11}} \leq l_1 \), then \( \overline{x}_1 < l_1 \) and \( \overline{x}_2 > u_2 \) we have \( x^* = (l_1, \min(\frac{b_2 - a_{12}l_1}{a_{22}}, l_2), u_2)^T \). Further we get

\[
\begin{align*}
\nabla q(x^*)_1 &\geq 0, \\
\nabla q(x^*)_2 &\geq 0, \quad \frac{b_2 - a_{12}l_1}{a_{22}} \leq l_1, \\
\nabla q(x^*)_2 &\leq 0, \quad l_2 < \frac{b_2 - a_{12}l_1}{a_{22}} < u_2, \\
\n\nabla q(x^*)_2 &\leq 0, \quad \frac{b_2 - a_{12}l_1}{a_{22}} \geq u_2
\end{align*}
\]

that is, \( x^* = (l_1, \min(\frac{b_2 - a_{12}l_1}{a_{22}}, l_2), u_2)^T \) satisfies KKT condition and has the form of expression (20). Thus, \( x^* \) is the unique global optimal solution of (19).

Case 5: If \( \overline{x}_1 < l_1 \) and \( l_2 \leq \overline{x}_2 \leq u_2 \), then \( x^* = (l_1, l_2)^T \).

The proof is similar to Case 3.

Case 6: If \( \overline{x}_1 < l_1 \) and \( \overline{x}_2 < l_2 \), then \( x^* = (l_1, l_2)^T \).
Proof: From $x_1 < 1$ and $x_2 < 2$ we have 
\[
\begin{align*}
\frac{a_1 - a_1 l_2}{a_{11}} &\geq \frac{b_1 - a_1 u_2}{a_{11}}, \\
\frac{a_2 - a_2 l_2}{a_{22}} &\geq \frac{b_2 - a_2 u_2}{a_{22}}.
\end{align*}
\]
Further we get $V(x^*) \geq 0$, that is $x^* = (l_1, l_2)^T$ satisfies KKT condition and has the form of expression (20). Therefore, $x^*$ is the unique global optimal solution of (19).

Case 7: If $l_1 \leq x_1 < 1$ and $x_2 < l_2$, then $x^* = (\max (\frac{b_2 - a_1 l_2}{a_{11}}, l_1), l_2)^T$. The proof is similar to Case 3.

Case 8: If $x_1 < 1$ and $x_2 > u_2$, then 
\[
x^* = \begin{cases} 
\left( \max \left( \frac{b_2 - a_1 l_2}{a_{11}}, l_1 \right), l_2 \right)^T, & \frac{b_1 - a_1 l_2}{a_{11}} > u_1 \\
\left( u_1, \min \left( \max \left( \frac{b_2 - a_1 u_2}{a_{22}}, l_2 \right), u_2 \right) \right)^T, & \frac{b_1 - a_1 u_2}{a_{11}} \geq u_1
\end{cases}
\]
The proof is similar to Case 4.

Case 9: If $x_1 > u_1$ and $l_2 \leq x_2 \leq u_2$, then $x^* = (\max (\frac{b_2 - a_1 l_2}{a_{11}}, l_1), l_2)^T$. The proof is similar to Case 3.

(ii) For $a_{12} < 0$, firstly we prove that for any real number $a, b, c$, the conclusion as follows is right.

(i) $\max [\min (a, c), \min (b, c)] = \min [\max (a, b), c]$
(ii) $\min [\min (a, b), c] = \min [\max (a, c), \max (b, c)]$.

Proof: (i) If $a \leq b$, then $\min (a, c) \leq \min (b, c)$, it is clear that the left and right of the conclusion (i) are equal to $\min (b, c)$; if $b < a$, then the left and right of the conclusion (i) are equal to $\min (a, c)$, thus the conclusion (i) is right; (ii) The proof is similar to (i).

Secondly, substituting $x_1 = y_1, x_2 = y_2$ into the problem (19), we have
\[
\begin{align*}
\min q(x) &= p(y) = \frac{1}{2} (y_1, y_2) \begin{pmatrix} a_{11} & -a_{12} \\ -a_{12} & a_{22} \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \\
&\quad - (b_1 - b_2)(y_1, y_2)^T \\
\text{s.t.} \quad &l_1 \leq y_1 \leq u_1, \\
&-u_2 \leq y_2 \leq -l_2, \quad l_i \leq u_i, \quad i = 1, 2
\end{align*}
\]
where $\begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = \begin{pmatrix} \frac{b_1 - a_1 u_2}{a_{11}} \\ \frac{b_2 - a_2 l_2}{a_{22}} \end{pmatrix} = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$. Finally, we derive the optimal solution of (19) as follows:
\[
x_1^* = y_1^* = \min \left( \max \left( l_1, \frac{b_1 - a_1 u_2}{a_{11}} \right), \max \left( \frac{b_1 - a_1 u_2}{a_{11}}, l_1 \right), u_1 \right)
\]
\[
x_2^* = -y_2^* = -\min \left( \max \left( -u_2, -\frac{b_2 - a_2 u_1}{a_{22}} \right), \max \left( -\frac{b_2 - a_2 u_1}{a_{22}}, -u_2 \right), -l_2 \right)
\]
In summary, $x^*$ is the optimal solution of (19) and has the form of expression (21).
Qi Zhang is currently a PhD student in the University of Chinese Academy of Sciences, Beijing, China. She is also a PhD student of the joint program between City University of Hong Kong and University of Chinese Academy of Sciences. Her current research interests include computational intelligence, research social network and scientometric analysis.

Jue Wang Associate Professor of Chinese Academy of Sciences. Research field concludes computational intelligence, decision analysis, economic forecasting. More than 70 papers had been published in “European Journal of Operational Research”, “Fuzzy Optimization and Decision Making”, ”Experts System with Application” and so on; 6 books are published in America IGI Global publisher, and The Scientific Publisher in China. As executive editors of “Economic Forecasting Science Series”, ”low carbon economy and Chinese development” etc. and editorial board member of many important international journals. Hosted and participated in a number of National Natural Science Fund project, the knowledge innovation project of Chinese Academy of Sciences, Ministry of science and technology project assessment project, the financial risk management project, large Petrochemical Industries.

Aiguo Lu She was born in Yicheng, ShanXi Province, China. She received her Ph.D. degree in Department of Mathematics from Xidian University. Her research interests include Support vector machines and Unconstrained Optimization Problems, and so on.

Shouyang Wang received the Ph.D. degree in operations research from Institute of Systems Science, Chinese Academy of Sciences (CAS), Beijing in 1986. He is currently a Bairen distinguished professor of Management Science at Academy of Mathematics and Systems Sciences of CAS and a Lotus chair professor of Hunan University, Changsha. He is the editor-in-chief or a co-editor of 12 journals. He has published 18 books and over 120 journal papers. His current research interests include financial engineering, e-auctions and decision support systems.

Jian Ma is Professor in Department of Information Systems at City University of Hong Kong. He is specialised in the research areas of research information systems, business intelligence and research social networks. He has published over 120 journal articles with SCI H index 22. His applied research work has been widely used in government funding agencies (e.g. National Natural Science Foundation of China) and universities (e.g. University of Hong Kong).
