Conclusions and Recommendations

The major objective of this study was to investigate the impacts of green building design and construction on construction worker safety and health. A comprehensive statistical analysis of 86 projects (38 green and 48 nongreen) tested the presence of a difference in safety performance between green and nongreen projects. Based on the above analyses of the study sample:

- There is suggestive but inconclusive evidence of a statistically significant difference between the median RIR of green and nongreen projects in the study sample. Green projects had a higher median RIR than nongreen projects.
- There is not a statistically significant difference between the median LTCRs for the green and nongreen projects included in the current study.
